## 1 **Review objective**

2 The objective of this review is to identify if high fidelity simulated learning methods are effective at  
3 enhancing clinical/practical skills compared to usual, low fidelity simulated learning methods in pre-  
4 registration physiotherapy education.

## 5 **Background**

6 Physiotherapy education ensures that students have the required knowledge and skills to practice as  
7 entry level physiotherapists upon graduation.<sup>1-4</sup> Consequently student physiotherapists require  
8 theoretical knowledge across a range of areas in addition to the ability to clinically reason, interact with  
9 patients and other members of the interdisciplinary team, provide education and advice as well as apply  
10 physical treatments.<sup>1-4</sup>

11 The pre-registration training of physiotherapists has traditionally incorporated college/university learning  
12 combined with clinical practice. During university-based learning there is usually a combination of  
13 theoretical and practical learning: The theory being learned in a normal classroom followed by practice  
14 of physical/practical skills on peers in an environment that replicates the outpatient environment with  
15 plinths, hand tables, stools and chairs. Practical learning for all key areas of physiotherapy practice  
16 (musculoskeletal, cardiovascular and neurological – in and outpatient) would be undertaken in the same  
17 setting. Students would then undertake periods of supervised practice in a clinical setting where they  
18 are expected to apply the theory and practical skills they have learned to the assessment and treatment  
19 of patients.

20 The physiotherapy profession advocates that pre-registration education ensures graduates are  
21 equipped to practice autonomously.<sup>5</sup> Consequently students are required to be able to undertake the  
22 duties of a physiotherapist including performing assessment and treatment skills, the application of  
23 clinical reasoning skills and effective communication and team working skills immediately upon  
24 graduation.<sup>1-5</sup> Although the various physiotherapy professional bodies indicate required course content,  
25 their recommendations about teaching and learning methods are more vague simply indicating that  
26 course teams should give consideration to teaching and learning methods that maximize learning and  
27 that prepare students well for initial practice.<sup>1,2</sup> In fact only the World Confederation for Physical  
28 Therapy (WCPT) mention how practical skills should be developed indicating that students should  
29 practice on each other, a form of low fidelity simulation.<sup>5</sup>

30 Isselberg and McGaghie<sup>6</sup> suggest that learning the cognitive knowledge required in practice is different

31 to the learning required for acquiring clinical/practical skills. They indicate that for the development of  
32 clinical/practical skills learners need to engage in repeated and deliberate practice and receive specific  
33 and focused feedback. This means students need to be active and engaged learners, something that  
34 is supported by Bland, Topping and Wood<sup>7</sup> who also indicate that students need to understand how the  
35 cognitive and psychomotor skills required for professional practice interact.

36 In the UK, healthcare has been driving a quality agenda for many years. It has a strong focus on the  
37 provision of effective, high quality but value for money care.<sup>8</sup> Additionally, patient safety is essential with  
38 this having been highlighted recently in the Francis Report<sup>9</sup> and the World Health Organization (WHO)  
39 developing a patient safety curriculum.<sup>10</sup> These drivers are reiterated in other countries, for example  
40 the Affordable Care Act.<sup>11</sup> The imperative to provide safe, effective and efficient high quality care in  
41 addition to increases in student numbers in some countries and reducing staff numbers in others is  
42 putting pressure on student placement opportunities due to challenges to provide sufficient supervision  
43 to ensure safety and still achieve the required workload.<sup>12-14</sup> It is therefore incumbent on providers of  
44 pre-registration university-based physiotherapy education to ensure students are as prepared as  
45 possible for clinical placement to reduce the workload on their clinical educators.

46 The principles of safe, effective and high quality care<sup>15</sup> must be inculcated in students from the  
47 commencement of their training. In higher education there is also a drive to provide high quality and  
48 effective education opportunities with the introduction of the National Student Survey in the UK, the  
49 Student Experience Survey in Australia and the Canadian University Survey Consortium survey for  
50 example.<sup>16-18</sup> This has resulted in the development of an enhancement environment where staff are  
51 encouraged to think about the most effective ways of helping students learn. In many areas there has  
52 been a move from methods where knowledge is simply transmitted to students, to those supported by  
53 theories of Androgogy that encourage students to be active and engaged learners whose learning is  
54 facilitated through social interaction, something that simulation is well placed to provide.<sup>7</sup>

55 Within medical and nursing education simulated practice for learning clinical skills has long been in  
56 place as it has been suggested it provides an opportunity to better prepare for clinical practice.<sup>19</sup>  
57 Simulated learning is defined as:

58 *'An array of structured activities that represent actual or potential situations in education and practice.*  
59 *These activities allow participants to develop or enhance their knowledge, skills and attitudes or to*  
60 *analyse and respond to realistic situations in a simulated environment'* <sup>20(pp32)</sup>

61 In physiotherapy education simulation has always been evident, at a basic level, through classrooms  
62 replicating outpatient settings, skills practice on peers and students undertaking role play to mimic  
63 patients.<sup>21</sup> This should, in essence, facilitate the development of practical skills.<sup>6</sup>

64 There is a continuum of simulation from low to high fidelity<sup>19</sup> with 'fidelity' referring to the reality of the  
65 simulation.<sup>22</sup> Low fidelity simulation would equate to students undertaking role play or allowing peers to  
66 practice on each other, techniques traditionally used in physiotherapy education. High fidelity  
67 simulation however would require involvement of others to take on the role of patients, in simulation  
68 terminology standardized patients.<sup>20</sup> Alternatively, it could involve using computerized manikins or even  
69 virtual simulation where a student engages in computer games that simulate clinical situations.<sup>20</sup> An  
70 additional consideration is the authenticity of the situation that is utilized. This relates to the processes  
71 students go through during the simulation mirroring those encountered in actual practice as closely as  
72 possible.<sup>22</sup> An example would be the challenge of having to teach a technique such as active cycle of  
73 breathing to somebody who has no knowledge of what it entails.

74 Bland, Topping and Tobbell suggest that learning is enhanced when the situation is both realistic and  
75 authentic.<sup>22</sup> This would indicate that learning should take place in an authentic and realistic setting and  
76 situation. Additionally it implies that simulation methods beyond practicing on peers may be more  
77 beneficial. A belief in this approach is evidenced through the increased use of simulated learning  
78 activities in medical and nursing education.<sup>23,24</sup> This has been supported, certainly in the United  
79 Kingdom, by the Department of Health: The Chief Medical Officer indicated that simulation is an  
80 important method of learning for safer patient care and that it needs to be more fully integrated into  
81 health care education.<sup>25</sup> Internationally there is also support, for example the large scale project  
82 undertaken in Australia by Wright, Moss, Watson and Rue.<sup>14</sup> As Gaba indicates, simulation is a  
83 technique that "replaces or amplifies real experiences with guided experiences, often immersive in  
84 nature, that evoke or replicates substantial aspects of the real world in a fully interactive fashion."<sup>26(pp126)</sup>  
85 In this way learners are encouraged to apply and understand the cognitive and psychomotor skills  
86 required in professional practice.

87 A brief literature search will show a growth in literature pertaining to the use of high fidelity simulation  
88 in physiotherapy education. This is in relation to outcomes such as the development of practical skills,  
89 communication skills, confidence and decision making.<sup>27-29</sup> Simulation can be a time consuming  
90 learning method as high fidelity simulation requires high staff to student ratios and well equipped  
91 simulated learning environments. Before we can continue to develop the evidence base it is necessary  
92 to review what has already been established to identify future research priorities.

93 A search for systematic reviews relating to simulation use in physiotherapy education in the JBI  
94 Database of Systematic Reviews and Implementation Reports, PEDRO, CINAHL, Medline,  
95 PROSPERO and The Cochrane Database of Systematic Reviews indicated that three reviews have  
96 been undertaken to date.<sup>30-32</sup> The most recent review, by Pritchard et al., reported on the use of  
97 simulated patients in physiotherapy education. However, they excluded studies that utilized near peer  
98 role play (where senior students enact the role of the patient with portrayal of appropriate patient

99 presentation for more junior students to assess or treat) and consequently may have excluded  
100 information on a potentially beneficial method of learning.<sup>30</sup> A brief literature search also shows that  
101 there has been literature published since this systematic review and that alternative uses of simulated  
102 patients have also been investigated and yet not included in this review.<sup>33</sup>

103 Mori et al. undertook a systematic review of the use of simulated learning experiences in physiotherapy  
104 entry-to-practice curricula however they excluded studies that focused on communication and  
105 interpersonal skills, an essential part of physiotherapy training.<sup>31</sup> They also undertook their literature  
106 search in 2013 and as a consequence any subsequent publications with alternative simulation methods  
107 were not included. The final review focused solely on the effectiveness of online technology in  
108 physiotherapy education but again the search was undertaken in 2013.<sup>32</sup>

109 This suggests that an up to date systematic review addressing the use of simulation across  
110 physiotherapy education is required. This should consider whether high fidelity simulation provides  
111 any advantage to the traditional low fidelity simulation learning methods in the development of practical  
112 skills and communication skills in addition to clinical reasoning and any other professional level skills  
113 such as time management.

## 114 **Inclusion criteria**

### 115 **Types of participants**

116 Studies that include pre-registration physiotherapy students will be considered for this review. Pre-  
117 registration courses may confer licensure or a Diploma, Honours, Masters (pre-registration) or doctoral  
118 degree. The level of qualification required for entry to the profession varies from country to country  
119 and consequently any studies that have used pre-registration students during their entry level training  
120 will be considered. Published research investigating the learning achieved by physiotherapy students  
121 during interprofessional learning activities will be included only where data specifically relating to  
122 physiotherapy students can be extracted.

123

### 124 **Types of intervention(s)**

125 This review will consider studies that evaluate high fidelity simulation. The definition of simulation to  
126 be used is that defined in the Healthcare Simulation Dictionary: "An array of structured activities that  
127 represent actual or potential situations in education and practice" that enable students to "enhance their  
128 knowledge, skills and attitudes or to analyze and respond to realistic situations in a simulated  
129 environment".<sup>20(pp31)</sup>

130 As this review aims to be comprehensive a wide range of simulated activities will be included:

- 131 • Simulated person - ' a person portraying a patient' <sup>20(pp32)</sup>
- 132 • Manikin-based simulation – 'the use of manikins to represent a patient' <sup>20 (pp21)</sup>
- 133 • Virtual simulation – 'the recreation of reality depicted on a computer screen' <sup>20(pp40)</sup>

134 Simulated person will encompass standardized patients, volunteer patients and near peer role play.  
135 These interventions may be supplemented by on-line study/skills packages, video demonstrations and  
136 by reflection on skills performance through video analysis. The simulated activities may be uni- or  
137 inter-professional but it must be possible to extract data specifically relevant to the physiotherapy  
138 students. Interventions included will be classed as high fidelity but this will be used in a broad way to  
139 encompass anything beyond the traditional low fidelity simulation methods used in physiotherapy  
140 education (peer practice/role play and paper patients). If a study has used both low and high fidelity  
141 methods they will be included only if the dominant component is high fidelity or if it is possible to  
142 separate information relating to the two methods.

143 Methods of portraying patients such as video clips may be incorporated into virtual learning resources  
144 or even in classroom activities to replace paper case studies. Consequently video case studies will  
145 be included. Additionally simulations of any frequency and/or intensity will be included.

#### 146 **Comparator**

147 The comparator is low fidelity simulation. Traditionally pre-registration physiotherapy education requires  
148 peers to take on the role of 'patient' in the form of role play and for skills to be practiced on peers  
149 wherever this is appropriate, activities which are low fidelity simulation. More invasive techniques such  
150 as endotracheal suction would not traditionally be practiced. As a consequence peer practice and peer  
151 role play will be the comparators in this systematic review. Paper patients/case studies will be a further  
152 comparator.

#### 153 **Outcomes**

154 Primary outcomes will be standardized objective measures of skills performance including but not  
155 limited to, peak force, force amplitude, oscillation frequency and the Assessment of Physiotherapy  
156 Practice.<sup>34</sup> Measures of clinical reasoning, self-efficacy, confidence, communication skills and  
157 professional skills such as team working and prioritization will be included. Any methods of measuring  
158 these outcomes will be included such as, but not limited to, standardized measures (for example  
159 Student Perception of Effective Teaching in Clinical Simulation (SPETCS), Attitudes Towards Health  
160 Care Teams Survey, Readiness for Interprofessional Learning (RIPL), Arizona Clinical Interviewing  
161 Rating Scale and Assessment of Physiotherapy Practice tool (APP)). Additionally measures developed  
162 by researchers specifically for their study will be included.

163 Secondary outcomes will be aspects such as perception of impact where the change is not actually  
164 measured but is reported by students in questionnaires using categorical data.

165 Outcomes may be measured pre and post intervention or only post intervention. This will be influenced

166 by the type of study.

### 167 **Types of studies**

168 This review will consider experimental study designs including randomized controlled trials (if available),  
169 non-randomized controlled trials, quasi-experimental, before and after studies, prospective cohort  
170 studies, case control studies and analytical cross sectional studies. Additionally studies which have  
171 used questionnaires to investigate student views and perceptions of learning will be included but only  
172 where quantitative data is available. Inclusion of this data may provide information about the value  
173 students place on high fidelity simulated activities which may be interesting to relate to actual impact  
174 on skills performance.

### 175 **Search strategy**

176 The search strategy aims to find both published and unpublished studies. A three-step search strategy  
177 will be utilized in this review. An initial limited search of Medline and CINAHL will be undertaken followed  
178 by analysis of the text words contained in the title and abstract, and of the index terms used to describe  
179 articles. A second search using all identified keywords and index terms will then be undertaken across  
180 all included databases. Thirdly, the reference list of all identified reports and articles will be searched  
181 for additional studies. Studies published in a language other than English will only be included if a  
182 translation is available as translation services are not available to the authors. Studies published  
183 between 1978 (when physiotherapy first became an autonomous profession in the UK) to the present  
184 will be considered for inclusion in this review.

185 The databases to be searched include:

186 CINAHL, Medline, Eric and AMED

187 The search for unpublished studies will include:

188 EThOS Networked Digital Library of Theses and Dissertations

189 Google Scholar

190 Initial keywords to be used will be:

191 Student, physiotherap\*, physical therap\*, educat\*, learn\*, teach\*, skill\* develop\*, simulat\*, patient  
192 simulat\*, standard\* patient\*, high fidelity simulat\*, computer simulat\*, on-line skills, virtual patient, part  
193 practice, feedback, role play.

### 194 **Assessment of methodological quality**

195 Papers selected for retrieval will be assessed by two independent reviewers for methodological  
196 validity prior to inclusion in the review using standardized critical appraisal instruments from the

197 Joanna Briggs Institute (JBI-SUMARI) (<http://joannabriggs.org/research/critical-appraisal-tools.html>). As  
198 appropriate, check lists for the following will be utilized: cohort studies (JBI Critical Appraisal Checklist  
199 for Cohort Studies), case series (JBI Critical Appraisal Checklist for Case Studies), case reports JBI  
200 Critical Appraisal Checklist for Case Reports), case control studies (JBI Critical Appraisal Checklist for  
201 Case Control Studies), randomized controlled trials studies (JBI Critical Appraisal Checklist for  
202 Randomized Controlled Trials) , quasi-experimental studies studies (JBI Critical Appraisal Checklist  
203 for Quasi-Experimental Studies). Any disagreements that arise between the reviewers will be  
204 resolved through discussion, or with a third reviewer.

## 205 **Data extraction**

206 Data will be extracted from papers included in the review by two independent reviewers using the  
207 standardized data extraction tool from JBI-MAStARI (Appendix I). The data extracted will include  
208 specific details about the interventions, populations, study methods and outcomes of significance to the  
209 review question and specific objectives.

210 Where data reported in primary studies is unclear or information is missing authors will be contacted to  
211 request clarification. For data that has only been reported in abstract, for example conference  
212 presentations, authors will again be contacted and requests made for full reports.

213 Data will be extracted by two reviewers. Where differences in data from both reviewers is identified  
214 differences will be discussed. Where agreement is not reached a third, independent reviewer will be  
215 review the data source. Their decision on data to be included will be final.

## 216 **Data synthesis**

217 Quantitative data will, where possible, be pooled in statistical meta-analysis using JBI-MAStARI. All  
218 results will be subject to double data entry. Effect sizes expressed as odds ratio (for categorical data)  
219 and weighted mean differences (for continuous data) and their 95% confidence intervals will be  
220 calculated for analysis. Heterogeneity will be assessed statistically using the standard Chi-square and  
221 also explored using subgroup analyses based on the different study designs included in this review.  
222 Where statistical pooling is not possible the findings will be presented in narrative form including tables  
223 and figures to aid in data presentation where appropriate.

## 224 **Conflicts of interest**

225 Nil
