Physical activity and exercise for people with Parkinson’s

Abstract
A growing body of evidence exists advocating the value of physical activity and exercise for people with Parkinson’s. Such is the importance of being active, participation in exercise is perceived to be of equal importance to medication in the long-term management of Parkinson’s. Despite a substantial body of evidence, the optimal prescription of exercise or mode of delivery remains underdetermined. This article aims to discuss the current evidence and provide guidance of prescription of exercise during each of three commonly-referred to stages of Parkinson’s: newly diagnosed, maintenance and complex.

Introduction
Parkinson’s is the fastest growing neurological condition, with a 50% predicted rise of people living with the condition by 2030 [1]. In the absence of a cure, interventions that aim to limit the rate of decline and promote quality of life are of paramount importance to researchers and clinicians alike. Interest in the value of physical activity (PA), including exercise, has grown exponentially due to its potential neurorestorative role, as well as its positive impact on slowing the rate of decline. It is therefore essential that all members of the multi-disciplinary team are aware of the benefits of both for people with Parkinson’s and can promote participation in activity by signposting individuals to local PA opportunities. This paper summarises the PA evidence and describes PA prescription of each of three commonly-referred to stages of Parkinson’s: newly diagnosed, maintenance and complex.

Physical activity is an umbrella term which encompasses bodily movements produced by skeletal muscles, including a wide range of behaviours like gardening, housework and leisure-related activities [2]. Exercise is a subcategory of physical activity, defined as activities which are planned, structured, and purposeful, with the intention of improving and/or maintaining one or more components of physical fitness [3]; the terms Exercise and Physical activity however are commonly used interchangeably and inconsistently in activity-based research.

Diagnostic stage
PA should form an integral part of Parkinson’s management from diagnosis, and should be perceived as equal importance to medication, not as complementary [4]. Owing to the heterogeneous nature of Parkinson’s, a personalised approach to PA is advocated [5]. Key messages at this stage are to promote a physically active focused lifestyle, supported by friends and the Parkinson’s community, to support the development of a long-term activity habit. Exercise should be prescribed in tandem with contextualised education, to support changes in physical activity behaviour, and to provide people with Parkinson’s with the knowledge and skills to self-manage their physical activity.

When prescribing physical activity, frequency, intensity, type of activity and time need to be carefully considered. Within the diagnostic phase exercise prescription should focus on supporting people with Parkinson’s to develop a regular physical activity habit of a minimum of 2.5 hours a week [6], developing confidence to participate in higher intensity exercise is also advocated at the early stages of Parkinson’s. Participation in moderate to high intensity exercise (65-85% of mHR) has been shown to be both safe and feasible for people with Parkinson’s [7] and is associated with potential neurorestorative effects. Animal studies and a small number of human-based studies have demonstrated that high intensity exercise promotes improved vascularisation through angiogenesis, as well as increased concentration of neurotrophic factors such as BDNF or GDNF which are essential for neuronal growth, and integrity [5]. 150 minutes of moderate to high intensity exercise is advocated such as Nordic walking, aerobics, and cycling each week.

Types of exercise should be varied reflecting the range of motor and non-motor symptoms that people present with, combined with individual preferences. Reflecting current guidelines, strength training should be undertaken two to three times a week targeting spinal, hip and knee extensors and ankle dorsiflexors, prescribed in a progressive manner, where both resistance and task complexity are incrementally increased [8]. Flexibility training should be undertaken twice a week focusing on the spine, upper and lower limbs, ensuring that amplitude of movement is maintained during functional tasks [4]. Similarly balance training should be conducted twice weekly including turning, and dynamic movements incorporating progressive dual and cognitive tasks [8]. Figure 1, the exercise wheel acts as a guide on the frequency and types of exercise to guide physical activity engagement.

Julie Jones, MSc, PGCert, BSc (Hons) MCSP, SFHEA, is a Senior Lecturer at the School of Health Sciences, Robert Gordon University, Aberdeen, UK, and Physiotherapist who specialises in Parkinson’s. In 2019 Julie was awarded a Clinical Academic Fellowship funded by Parkinson’s UK and the Chief Scientist Office to undertake her PhD. ORCID: https://orcid.org/0000-0003-1943-1508

Katherine Baker, PhD, is Head of Subject for Physiotherapy in the Department of Sport, Exercise & Rehabilitation, Northumbria University, UK, and has a special interest in supporting those living with long term conditions, particularly Parkinson’s. To remain physically active. ORCID: https://orcid.org/0000-0003-4216-6298

Bhanu Ramaswamy, OBE, FCSP, DProf, is an Independent Physiotherapist Consultant and Visiting Fellow at Sheffield Hallam University, UK. She specialises in rehabilitation and physical activity engagement with older people with long term conditions and has contributed to book chapters and research in these areas. Bhanu is Co-Founder of the Exercise Professional’s Hub for the UK Parkinson’s Excellence Network. ORCID: https://orcid.org/0000-0001-9707-7597

Ensuring that functional movement is a key approach used to achieve this may need to always have a manageable exercise plan. It may be important to have options so the individual can choose when they are active while also ensuring that body and mind are engaged so as to preserve memory, attention and learning and to aid the management of non-motor symptoms such as sleep and mood. Exercise professionals should be aware that motor symptoms can put individuals at risk of injury so care should be taken to prepare individuals appropriately for exercise. Physical activity should be prescribed to a greater extent [17].

Little quantitative research exists to demonstrate the benefits of continuing exercise past Hoehn and Yahr Phase 3 due to the increasing complexity of the condition, however, the lived experience of people with Parkinson’s repeatedly illustrates the importance of maintaining an exercise routine for both physical and mental health, particularly if unable to access their usual programmes [14].

The people with Parkinson’s and those supporting them, who contributed towards the development of the Parkinson’s UK Exercise Framework spoke of the difficulties in maintaining a sufficient dosage of exercise to manage physical challenges as their condition progressed, but some exercise was viewed as essential in preserving fitness and functional daily activities where possible and managing the discomfort from likely postural changes [15]. Alterations to physical and mental ability necessitate an emphasis on increased support from others to assist the person with Parkinson’s with exercise, particularly for transfers and gait related activities [16]. As mobility impairments compromise safety, exercise should become more chair based using free weights and stationery equipment e.g. pedallers, plus be supervised to a greater extent [17].

Whilst still adhering to the Parkinson’s specific principles of exercising at maximal effort, amplitude and power, attention should be paid to the following:

1. Ensuring that functional movement is a key component of exercise routines e.g. sit to stand, turning in bed, overcoming episodes of freezing – all of which may need additional training of movement strategies or cueing techniques.

2. Respiratory complications are the highest cause of mortality in people with Parkinson’s. As bradykinesia and rigidity affect lung function [18], respiratory exercises should be added to any exercise routine [19].

Conclusion

Physical activity should form an integral part of the management of people with Parkinson’s from diagnosis. Like medication, physical activity prescription needs to reflect individual needs, and should encompass strength, flexibility, balance, aerobic, and functional based exercise. Physical activity should be prescribed in parallel with contextualised education to provide the person with adequate knowledge and skills to develop a sustained physical activity habit.
